

Table 2.4 Temporary Seeding for Site Stabilization

Plant Species	Seeding Rate ¹		Seeding Depth	Recommended Seeding Dates	
- India operator	lb/ac	lb/1,000 ft ²	(inches) ²	Plant Hardiness Zone 7a and 7b ³	
		Co	ol-Season Grasses		
Annual Ryegrass	40	1.0	0.5	Feb. 15 to Apr. 30; Aug. 15 to Nov. 30	
Barley	96	2.2	1.0	Feb. 15 to Apr. 30; Aug. 15 to Nov. 30	
Oats	72	1.7	1.0	Feb. 15 to Apr. 30; Aug. 15 to Nov. 30	
Wheat	120	2.8	1.0	Feb. 15 to Apr. 30; Aug. 15 to Nov. 30	
Cereal Rye	112	2.8	1.0	Feb. 15 to Apr. 30; Aug. 15 to Dec. 15	
		Wa	rm-Season Grasses		
Foxtail Millet	30	0.7	0.5	May 1 to Aug. 14	
Pearl Millet	20	0.5	0.5	May 1 to Aug. 14	

¹Seeding rates for the warm-season grasses are in pounds of pure live seed (PLS). Actual planting rates must be adjusted to reflect percent seed germination and purity, as tested. Adjustments are usually not needed for the coolseason grasses.

Seeding rates listed above are for temporary seedings, when planted alone. When planted as a nurse crop with permanent seed mixes, use 1/3 of the seeding rate listed above for barley, oats, and wheat. For smaller-seeded grasses (annual ryegrass, pearl millet, foxtail millet), do not exceed more than 5% (by weight) of the overall ermanent seeding mix. Generally, do not use cereal rye as a nurse crop unless planting will occur in very late fall beyond the seeding dates for other temporary seedings. Cereal rye has allelopathic properties that inhibit the germination and growth of other plants. If it must be used as a nurse crop, seed at 1/3 of the rate listed above. Oats are the recommended nurse crop for warm-season grasses.

²For sandy soils, plant seeds at twice the depth listed above. ³The planting dates listed are averages and may require adjustment to reflect local conditions.

Table 2.5 Permanent Seeding Summary

			Perm	anent Seed	ing Summa	ry		
	Seed Mixture			Fertilizer Rate (10-20-20)				
No.	Species	Application Rate (lb/ac)	Seeding Dates	Seeding Depths	N	P ₂ 0 ₅	K ₂ 0	Lime Rate
					45 lb/ac	90 lb/ac	901b/ac	2 tons/ac
					(1.0 lb/ 1,000 ft²)	(2 lb/ 1,000 ft ²)	(2 lb/ 1,000 ft ²)	(90 lb/ 1,000 ft ²)

Select a seed mixture from Table 2.6, using Table 2.7 (conditions by mix) as a guideline. Some guidance for common mixes is as follows:

- Kentucky Bluegrass (full sun mixture) For use in areas that receive intensive management. The recommended certified Kentucky bluegrass cultivars seeding rate is 1.5 to 2.0 pounds per 1.000 square feet. Choose a minimum of three bluegrass cultivars ranging from a minimum of 10% to a maximum of 35% of the mixture by weight.
- 2. Kentucky Bluegrass/Perennial Rye (full sun mixture) For use in full sun areas where rapid establishment is necessary and when turf will receive medium to intensive management. The certified perennial ryegrass cultivars/certified Kentucky bluegrass seeding rate is 2 pounds mixture per 1,000 square feet. A minimum of three Kentucky bluegrass cultivars must be chosen, with each cultivar ranging from 10% to 35% of the mixture by weight.
- 3. Tall Fescue/Kentucky Bluegrass (full sun mixture) For use in drought prone areas and/or for areas receiving low to medium management in full sun to medium shade. The recommended mixture includes 95% to 100% certified tall fescue cultivars and 0% to 5% certified Kentucky bluegrass cultivars. The seeding rate is 5 to 8 pounds per 1,000 square feet. One or more cultivars may be blended.
- 4. Kentucky Bluegrass/Fine Fescue (shade mixture) For use in areas with shade in bluegrass lawns or for establishment in high quality, intensively managed turf area. The mixture includes 30% to 40% certified Kentucky bluegrass cultivars and 60% to 70% of certified fine fescue. The seeding rate is 1½ to 3 pounds per 1,000 square feet. A minimum of 3 Kentucky bluegrass cultivars must be chosen, with each cultivar ranging from a minimum of 10% to a maximum of 35% of the mixture by weight.

Note: Select turfgrass varieties from those listed in the most current Maryland-Virginia Turfgrass Variety Recommendation Work Group list (http://www.pubs.ext.vt.edu/).

Use sod grass to provide quick cover on disturbed areas (2:1 grade or flatter).

- 1. Class of turfgrass sod must comply with the grass varieties listed in Table 2.7. Make sod labels available to the job foreman and inspector 2. Machine cut sod at a uniform soil thickness of \(^3\)4 inches, plus or minus \(^4\)4 inches, at the time
- of cutting. Measurement for thickness must exclude top growth and thatch. Individual pieces of sod must be cut to the supplier's width and length. Maximum allowable deviation from standard widths and lengths is 5%. Broken pads and torn or uneven ends will not be
- 3. Standard size sections of sod must be strong enough to support their own weight and retain their size and shape when suspended vertically with a firm grasp on the upper 10% of the
- 4. Do not harvest or transplant sod when moisture content (excessively dry or wet) may adversely affect its survival.
- 5. Harvest, deliver, and install sod within a period of 36 hours. Sod not transplanted within this period must be approved by an agronomist or soil scientist prior to its installation.

Planting Dates

The recommended planting dates for permanent cover can be found in Table 2.8.

Sod - Cool-Season	Feb 15 to Apr 30 May 1 to Sep 30 ⁵ Oct 1 to Dec 1 ^{5, 6}			

- 1. When seeding toward the end of the listed planting dates, or when conditions are expected to be less than
- optimal, select an appropriate nurse crop from Table 2.4 Temporary Seeding for Site Stabilization and plant ogether with the permanent seeding mix. 2. When planted during the growing season, most of these materials must be purchased and kept in a dormant
- condition until planting. Recommend adding a nurse crop, as noted above, if planting during this period.

have not sufficiently rooted in place. Sod usually needs 4 to 6 weeks to become sufficiently rooted

- Warm-season grasses need a soil temperature of at least 50 degrees F in order to germinate. If soil temperatures are colder than 50 degrees, or moisture is not adequate, the seeds will remain dormant until conditions are favorable. In general, planting during the latter portion of this period allows more time for weed emergence and weed control prior to planting. When selecting a planting date, consider the need for weed control vs. the
- likelihood of having sufficient moisture for later plantings, especially on droughty sites. Additional planting dates during which supplemental watering may be needed to ensure plant establishmen Frequent freezing and thawing of wet soils may result in frost-heaving of materials planted in late fall, if plants

Minimum Soil Criteria

- Minimum soil conditions required for permanent vegetative establishment include the following:
- Soil pH must be between 6.0 and 7.0.
- 2. Soluble salts must be less than 500 parts per million (ppm).
- 3. The soil must contain less than 40% clay but enough fine grained material (> 30% silt plus clay) to provide the capacity to hold a moderate amount of moisture. As an exception, it is acceptable to plant lovegrass or serecia lespedeza in sandy soil (< 30% silt plus clay).
- 4. Soil must contain 1.5% minimum organic matter by weight.
- 6. If these conditions cannot be met by soils on site, topsoil must be added as required in Section 2.6 Topsoiling

5. Soil must contain sufficient pore space to permit adequate root penetration.

Soil Amendments (Fertilizer and Lime Specifications)

- 1. Soil tests must be performed to determine the exact ratios and application rates for both lime and fertilizer on sites with disturbed areas over 5 acres. Soil analysis may be performed by the University of the District of Columbia or a certified commercial laboratory. Soil samples taken for engineering purposes may also be used for chemical analyses.
- 2. Fertilizers must be uniform in composition, free flowing, and suitable for accurate application by approved equipment. Manure may be substituted for fertilizer with prior approval from DOEE. Deliver all fertilizers to the site fully labeled per applicable laws and bear the name, trade name or trademark, and warranty of the producer.
- 3. Lime materials must be ground limestone (hydrated or burnt lime may be substituted) containing at least 50% total oxides (calcium oxide plus magnesium oxide). Limestone must be ground to such fineness that at least 50% will pass through a #100 mesh sieve and 98% to 100% will pass through a #20 mesh sieve.

2.10.5 Construction Specifications

Site Preparation

- 1. Install erosion and sediment control structures (either temporary or permanent) such as diversions, grade stabilization structures, berms, waterways, or sediment control basins.
- 2. Perform all grading operations at right angles to the slope. Final grading and shaping is not usually necessary for temporary seeding
- 3. Schedule required soil tests to determine soil amendment composition and application rates for sites having disturbed area over 5 acres.
- 4. Distribute lime and fertilizer evenly and incorporate them into the top 3 to 5 inches of soil by disking or other suitable means.
- 5. Where the subsoil is either highly acidic or composed of heavy clays, spread ground limestone at the rate of 4 to 8 tons per acre (200 to 400 pounds per 1,000 square feet) prior to the placement of topsoil.

Seedbed Preparation

Temporary Seeding

(a) Seedbed preparation must consist of loosening soil to a depth of 3 to 5 inches by means of suitable agricultural or construction equipment, such as disc harrows or chisel plows or rippers mounted on construction equipment. After the soil is loosened, do not roll or drag smooth but leave in the roughened condition. Track sloped areas (greater than 3:1) leaving the surface in an irregular condition with ridges running parallel to the contour of

(b) Apply fertilizer and lime as prescribed on the plans.

- (c) Incorporate lime and fertilizer into the top 3 to 5 inches of soil by disking or other
- 2. Permanent Seeding Maintain areas previously graded in conformance with the drawings in a true and even grade, then scarified or otherwise loosened to a depth of 3 to 5 inches to permit bonding of the topsoil to the surface area and to create horizontal erosion check slots to prevent topsoil from sliding down a slope.

Apply soil amendments as per soil test or as included on the plans. Mix soil amendments into the top 3 to 5 inches of topsoil by disking or other suitable means. Rake lawn areas to smooth the surface, remove large objects like stones and branches, and ready the area for seed application. Where site conditions will not permit normal seedbed preparation, loosen surface soil by dragging with a heavy chain or other equipment to roughen the surface. Track steep slopes (steeper than 3:1) by a dozer leaving the soil in an irregular condition with ridges running parallel to the contour of the slope. The top 1 to 3 inches of soil should be loose and friable. Seedbed loosening may not be necessary on newly disturbed areas.

3. Methods of Seeding - Apply seed uniformly with hydroseeder (slurry includes seed, fertilizer and mulch), broadcast or drop seeder, or a cultipacker seeder.

i) If fertilizer is being applied at the time of seeding, the application rates will not nitrogen; P_2O_5 (phosphorous), 200 pounds per acre; K_2O (potassium), 200 pounds per

ii) Lime – Use only ground agricultural limestone, (up to 3 tons per acre may be applied by hydroseeding). Normally, not more than 2 tons per acre are applied by hydroseeding at any one time. Do not use burnt or hydrated lime when hydroseeding.

iii) Seed and fertilizer must be mixed on site and seeding must be done immediately and without interruption.

iv) Fiber mulch may be incorporated into the hydroseeding mixture. Consult Section 2.7

Mulching for standards and specifications for mulch materials. (b) Dry Seeding – This includes use of conventional drop or broadcast spreaders.

- i) Incorporate seed spread dry into the subsoil at the rates prescribed on the Temporary or Permanent Seeding Summaries or Tables 2.4 or 2.7. The seeded area must then be rolled with a weighted roller to provide good seed to soil contact.
- ii) Where practical, apply seed in two directions perpendicular to each other. Apply half the seeding rate in each direction.
- (c) Drill or Cultipacker Seeding Mechanized seeders that apply and cover seed with soil. i) Cultipacking seeders are required to bury the seed in such a fashion as to provide at
- least ¼ inches of soil covering. Seedbed must be firm after planting. ii) Where practical, apply seed in two directions perpendicular to each other. Apply half
- the seeding rate in each direction. 4. Sod Installation – During periods of excessively high temperature or in areas having dry

subsoil, the subsoil must be lightly irrigated immediately prior to laying the sod. The first row of sod must be laid in a straight line with subsequent rows placed parallel to and tightly wedged against each other. Lateral joints must be staggered to promote more uniform growth and strength. Ensure that sod is not stretched or overlapped and that all joints are butted tight in order to prevent voids, which would cause air drying of the roots. Wherever possible, lay sod with the long edges parallel to the contour and with staggering joints. Roll and tamp, peg, or otherwise secure sod to prevent slippage on slopes and to

ensure solid contact between sod roots and the underlying soil surface. Immediately water sod following rolling or tamping until the underside of the new sod pad and soil surface below the sod are thoroughly wet. Complete the operations of laying, tamping and irrigating for any piece of sod within eight hours.

5. Incremental Stabilization - Cut Slopes

Dress, prepare, seed, and mulch all cut slopes as the work progresses. Excavate and stabilize slopes in equal increments not to exceed 15 feet. The construction sequence is as follows (refer to Figure 2.1):

(a) Excavate and stabilize all temporary swales, side ditches, or berms that will be used to convey runoff from the excavation.

(b) Perform phase 1 excavation, dress, and stabilize.

(c) Perform phase 2 excavation, dress, and stabilize. Overseed phase 1 areas as necessary. (d) Perform final phase excavation, dress, and stabilize. Overseed previously seeded areas as

Note: Once excavation has begun the operation should be continuous from grubbing through the completion of grading and placement of topsoil (if required) and permanent seed and mulch. Any interruptions in the operation or completing the operation out of the seeding season will necessitate the application of temporary stabilization.

- Grass Maintenance 1. Inspect all seeded areas for failures and make necessary repairs, replacements, and reseedings
- 2. Once the vegetation is established, the site must have 95% ground cover to be considered
- 3. If the stand provides less than 40% ground coverage, reestablish following original lime, fertilizer, seedbed preparation and seeding recommendations
- 4. If the stand provides between 40% and 94% ground coverage, overseeding and fertilizing using half of the rates originally applied may be necessary
- 5. Maintenance fertilizer rates for permanent seedings are shown in Table 2.9.

Table 2.9 Maintenance Fertilization for Permanent Seeding

luegrass, hard escue mixtures.	20-10-10	100	2.3	December, May 20, June 30, if needed.	bluegrass, 3 inches for fescue	

Sod Maintenance

- 1. In the absence of adequate rainfall, perform watering daily or as often as necessary during the first week and in sufficient quantities to maintain moist soil to a depth of 4 inches. Water during the heat of the day to prevent wilting 2. After the first week, sod watering is required as necessary to maintain adequate moisture
- 3. Do not attempt the first mowing of sod until the sod is firmly rooted. Do not remove more than a third of the grass leaf by the initial cutting or subsequent cuttings. Maintain grass height between 2 to 3 inches unless otherwise specified.

2.6 Topsoiling

2.6.1 Definition

Placement of topsoil over prepared subsoil prior to establishing permanent vegetation.

2.6.2 Purpose

To provide a suitable soil medium for vegetative growth.

2.6.3 Conditions Where Practice Applies

This practice is recommended for areas with 2:1 or flatter slopes where one or more of the

- following apply: 1. The texture, pH, or nutrient balance of the exposed subsoil/parent material is not adequate to produce vegetative growth.
- 2. The soil material is so shallow that the rooting zone is not deep enough to support plants or
- furnish continuing supplies of moisture and plant nutrients.
- 3. The original soil to be vegetated contains material toxic to plant growth. The soil is so acidic that treatment with limestone is not feasible.
- Areas having slopes steeper than 2:1 require special consideration and design for adequate

stabilization. These areas must have the appropriate stabilization shown on the plans.

Topsoil salvaged from the existing site may be used if it meets the standards in these specifications. Place topsoil and apply soil amendments as specified in Section 2.10 Vegetative Stabilization. Soil to be used as topsoil must meet the following specifications:

- 1. Topsoil must be a loam, sandy loam, clay loam, silt loam, sandy clay loam, or loamy sand. Other soils may be used if recommended by an agronomist or soil scientist and approved by DOEE. Regardless, topsoil must not be a mixture of contrasting textured subsoils and must contain less than 5% by volume of cinders, stones, slag, coarse fragments, gravel, sticks, roots, trash, or other materials larger than 1 inch in diameter.
- 2. Topsoil must be free of noxious plants or plant parts such as Bermuda grass, quackgrass, Johnsongrass, nutsedge, poison ivy, thistle, other poisonous plants, or others as specified in Section 2.10 Vegetative Stabilization. Topsoil must also be free from invasive plants or plant
- 3. Where the subsoil is either highly acidic or composed of heavy clays, spread ground placement of topsoil. Distribute lime uniformly over designated areas and work into the soil in conjunction with tillage operations as described in the next step.

For sites with disturbed areas over 5 acres, obtain test results dictating fertilizer and lime amendments required to bring the soil into compliance with the requirements set forth in Section 2.10 Vegetative Stabilization. Alternatives to natural topsoil and alternative soil amendments, such as composted sewage sludge or other composted materials, may be used in place of fertilizer and lime, as allowed by other applicable regulations and as approved by a certified

2.6.5 Construction Specifications

- 1. When topsoiling, maintain needed erosion and sediment control practices such as diversions,
- grade stabilization structures, earth dikes, silt fence, and sediment traps and basins. 2. Grades on the areas to be topsoiled, which have been previously established, must be
- maintained, though now with an additional 4 to 8 inches height in elevation. 3. After the areas to be topsoiled have been brought to grade, and immediately prior to dumping and spreading the topsoil, loosen the subgrade by discing or by scarifying to a depth of a least 4 inches to permit bonding of the topsoil to the subsoil. Pack the subsoil by passing a
- bulldozer up and down over the entire surface area of the slope to create horizontal erosion check slots to prevent topsoil from sliding down the slope. 4. Uniformly distribute topsoil in a 4-inch to 8-inch layer and lightly compact to a minimum thickness of 4 inches. Perform spreading in such a manner that sodding or seeding can proceed with a minimum of additional soil preparation and tillage. Correct any irregularities in the surface resulting from topsoiling or other operations to prevent the formation of
- depressions or water pockets. 5. Do not place topsoil while the topsoil or subsoil is in a frozen or muddy condition, when the subsoil is excessively wet, or in a condition that may otherwise be detrimental to proper grading and seedbed preparation.

2.6.6 Maintenance

After precipitation events, confirm that topsoil and subsoil are properly bonded and no sloughing

2.7 Mulching

2.7.1 Definition

The application of a protective layer of mulch or other suitable material to the soil surface.

To protect the soil surface from the forces of raindrop impact and overland flow. Mulch helps to conserve moisture, reduce runoff and erosion, control weeds, prevent soil crusting, and promote the establishment of desired vegetation. Mulch is frequently used to accent landscape plantings.

2.7.3 Conditions Where Practice Applies

Mulching can be used at any time where protection of the soil surface is desired. The primary purpose of mulching is to protect newly seeded disturbed areas. However, it can also be used for stand-alone protection of the soil surface under adverse weather conditions when seed germination could be jeopardized. Mulch may also be used together with plantings of trees, shrubs, or certain ground cover that do not provide adequate soil stabilization by themselves.

Use mulching in conjunction with temporary seeding operation as specified in Section 2.10 Vegetative Stabilization.

2.7.4 Design Criteria

A surface mulch is the most effective, practical means of controlling runoff and erosion on disturbed land prior to vegetation establishment. Mulch reduces soil moisture loss by evaporation, prevents crusting and sealing of the soil surface, moderates soil temperatures, provides a suitable microclimate for seed germination, and may increase the infiltration rate of

Organic mulches such as straw, wood chips, and shredded bark have been found to be the most effective. Do not use materials that may be sources of competing weed and grass seeds. Be aware that decomposition of some wood products can tie up significant amounts of soil nitrogen, making it necessary to modify fertilization rates or add fertilizer with the mulch.

Various types of netting materials are available to anchor organic mulches. Chemical soil stabilizers or soil binders are less effective than other types of mulches when used alone. These products are primarily useful for tacking wood fiber mulches.

Choose materials for mulching based on soil conditions, season, type of vegetation, and size of the area. A properly applied and tacked mulch is always beneficial. It is especially important when conditions for germination are not optimum, such as midsummer and early winter, and on difficult areas such as cut slopes and slopes with southern exposures.

1. Straw must be unrotted small grain straw. Mulch materials must be relatively free of weeds and must be free of noxious weeds such as thistles, Johnsongrass, and quackgrass. Spread

mulch uniformly by hand or mechanically. Straw can be windblown and must be anchored

down by an acceptable method. 2. Wood chips are particularly well suited for utility and road rights-of-way, as well as areas that will not be closely mowed or around ornamental plantings. Wood chips do not require tacking. Because they decompose slowly, they must be treated with 12 pounds of nitrogen per ton to prevent nutrient deficiency in plants. Mulch can be inexpensive if chips are

obtained from trees cleared on the site. 3. Wood fiber consists of specially prepared wood cellulose processed into a uniform fibrous physical state. It is used in hydroseeding operations and applied as part of a slurry. It creates the best seed-soil contact when applied over top of (as a separate operation) newly seeded areas. These fibers do not require tacking, although tacking agents or binders are sometimes used in conjunction with the application of fiber mulch. The following conditions apply to

(a) Wood fiber is to be dyed green or contain a green dye in the package that will provide an

- appropriate color to facilitate visual inspection of the uniformly spread slurry. (b) Wood fiber, including dye, must contain no germination or growth inhibiting factors. (c) Wood fiber materials are to be manufactured and processed in such a manner that the wood cellulose fiber mulch will remain in uniform suspension in water under agitation and will blend with seed, fertilizer, and other additives to form a homogeneous slurry. The mulch material must form a blotter-like ground cover on application, having moisture absorption and percolation properties, and must cover and hold grass seed in
- contact with the soil without inhibiting the growth of the grass seedlings. (d) Wood fiber material must not contain elements or compounds at concentration levels that will be phytotoxic.

approximately 10 millimeters, diameter of approximately 1 millimeter, pH range of 4.0 to 8.5, ash content of 1.6% maximum, and water holding capacity of 90% minimum.

1. Prior to mulching, install any needed erosion and sediment control practices such as

(e) Wood fiber must conform to the following physical requirements: fiber length of

- diversions, grade stabilization structures, berms, channels, and sediment traps and basins. 2. Apply seed and soil amendments at required rates to bring the soil into compliance with the requirements set forth in Section 2.10 Vegetative Stabilization
- 3. Apply mulch at required rates. Depending on site conditions, hydraulically applied mulches may be applied in a one-step process where all components may be mixed together in single tank loads. Consult with the manufacturer for further details. (a) Straw - Apply straw mulch over all seeded areas at the rate of 2 tons per acre, or 2 bales
- per 1,000 square feet, to a uniform loose depth of 1 to 2 inches. Apply so that the soil surface is not exposed. (b) Wood chips – Apply wood chips at the rate of approximately 10-20 tons per acre or 500
- to 900 pounds per 1,000 square feet; the depth should be 2 to 7 inches. (c) Wood cellulose fiber – Apply wood cellulose fiber at a dry weight rate of 2,000 pounds per acre. Mix the wood cellulose fiber with water to attain a mixture with a maximum of 50 pounds of wood cellulose fiber per 100 gallons of water. Wood cellulose fiber is not typically used on slopes steeper than 5%. For steeper slopes, apply at rates or in conjunction with tackifiers per manufacturer's specifications based on slope and other site characteristics. In hydroseeding operations, a green dye added to the slurry assures a
- uniform application.
- 4. Anchor mulch immediately following application to minimize loss by wind or water. Depending upon the size of the area and erosion hazard, use one of the following methods: (a) Mulch anchoring tool – A mulch anchoring tool is a tractor drawn implement designed to punch and anchor mulch into the soil surface a minimum of 2 inches. This practice is
- most effective on large areas, but is limited to flatter slopes where equipment can operate safely. If used on sloping land, this practice should follow the contour. (b) Liquid mulch binders – Application of liquid mulch binders and tackifiers should be heaviest at the edges of areas and at crests of ridges and banks to resist wind. Apply binder uniformly to the rest of the area. Binders may be applied after mulch is spread, or it may be sprayed into the mulch as it is being blown onto the soil. Applying straw and
- binder together is the most effective method. (c) Synthetic binders – Synthetic binders must follow the application rates specified by the manufacturer. Application of liquid binders needs to be heavier at the edges where wind catches mulch, such as in valleys and on crests of banks. Use of asphalt binders is strictly
- (d) Netting Lightweight plastic, cotton, jute, wire, or paper nets may be stapled over the
- mulch according to the manufacturer's recommendations (e) Mats - Mats promote seedling growth in the same way as organic mulches. They are very useful in establishing grass in channels and waterways. A wide variety of synthetic and organic materials are available. "Excelsior" is a wood fiber mat that should not be
- confused with wood fiber slurry (see Section 2.9 Rolled Erosion Control Products). 5. When installing nets and mats, it is critical to obtain a firm, continuous contact between the material and the soil. Without such contact, the material is useless, and erosion will occur underneath. Any mat or blanket-type product used as a protective mulch should provide cover of at least 30% of the surface where it is applied.
- (a) Apply lime, fertilizer, and seed before laying the net or mat. (b) Start laying the net from the top of the slope and unroll it down the grade. Allow netting
- to lay loosely on the soil or mulch cover but without wrinkles—do not stretch. (c) To secure the net, bury the upslope end in a slot or trench no less than 6 inches deep, cover with soil, and tamp firmly. Staple the net every 12 inches across the top end and every 3 feet around the edges and bottom. Where 2 strips of net are laid side by side, overlap the adjacent edges 3 inches and staple together. Each strip of netting should also be stapled down the center, every 3 feet. Do not stretch the net when applying staples.

(d) To join two strips, cut a trench to anchor the end of the new net. Overlap the end of the

previous roll 18 inches, and staple every 12 inches just below the anchor slot.

Periodically inspect all mulches and soil coverings to check for erosion, particularly after precipitation events. Where erosion is observed in mulched areas, apply additional mulch. Inspect nets and mats after rainstorms for dislocation or failure. If washouts or breakage occur, reinstall netting or matting as necessary after repairing damage to the slope or ditch. Inspections should take place until grasses are firmly established. Where mulch is used in conjunction with ornamental plantings, inspect periodically throughout the year to determine if mulch is maintaining coverage of the soil surface; repair as needed.

Construction Specifications for Dust Control

- 1. The contractor must conduct operations and maintain the project site so as to minimize the creation and dispersion of dust.
- Use dust control throughout the work at the site The contractor must provide clean water, free from salt, soil, and other deleterious material to be used for on-site dust
- The contractor shall supply water-spraying equipment capable of accessing all work area. 4. The contractor shall implement strict dust control measures during active construction periods on-site. These control
- measures shall generally consist of water applications that shall be applied a minimum of once per day during dry weather or more often as required to prevent dust emissions. 5. For water application to undisturbed soil surfaces, the contractor shall:
- 5.a. Apply water with equipment consisting of tank, spray bar, and pump with discharge pressure gauge.
- 5.b. Arrange spray bar height, nozzle spacing, and spray pattern to provide complete coverage of ground with water.
- Disperse water through nozzles on spray bar at 20 psi (137.8 kPa) minimum. Keep areas damp without creating nuisance conditions such as ponding. 6. For water application to soil surfaces during demolition and/or excavation, the contractor shall:
- 6.a. Apply water with equipment consisting of a tank, pump with discharge gauge, hoses, and mist nozzles 6.b. Locate tank and spraying equipment so that the entire excavation area can be misted without interfering with demolition and/or excavation equipment or operations. Keep areas damp without creating nuisance conditions such as
- Construction Sequence Notes

6.c. Apply water spray in a manner to prevent movement of spray beyond the site boundaries.

- 1. Sediment traps or basins and other erosion and sediment controls shall be installed no later than the first phase of land Sediment traps or basins and other erosion and sediment controls shall be, installed as soon as new site-related runoff is
- detected and employed at all times to protect inlets or storm sewers below silt-producing areas 3. Immediately after debris basins, diversions, waterways, and related structures are built seed and mulch, or install sod &
- 4. No later than the first day of construction install site access measures to minimize off-site vehicle tracking of sediments. Each construction entrance must be stabilized and include each additional measure required to keep sediment from being carried, onto public streets by construction vehicles, and washed into a storm drain or waterways Remove off-site accumulations of sediment daily during construction and immediately at the request of a DOEE inspector.
- Notes for Underground Utility Work

Use mulch and matting on excavated material to minimize their erosion when natural or artificial grass filter strips are

1. When conducting underground utility work do not open more than five hundred linear feet (500 ft) of trench at any one Filter water pumped out of trench excavations prior to discharging to the storm sewer system.

. Perform routine maintenance to prevent any new destabilized areas.

- Place excavated material for utility work on the uphill side of a tren Install interim or permanent stabilization immediately after a utility trench is refilled.
- installed to receive stormwater runoff from the excavated materials. Notes for Roadway Projects
- 1. Rough graded rights-of-way awaiting installation of utilities or pavement shall be protected by the installation of interceptor dikes across rights-of-way, with spacing of five hundred feet (500 ft) or less between the dikes. The DOFF reviewer may approve alternative controls recommended a DC-licensed PE.
- The ESC plan must demonstrate how temporary diversion dikes and flumes, or alternative controls recommended by a DC-licensed PE, will convey runoff down cut-and-fill slopes to an DOEE approved outlet 3. The ESC plan must demonstrate how a permanent drainage structure, including diversions at top-of-slope cuts and diversions to convey runoff to a storm sewer or other suitable outlet, shall be installed at the completion of rough grading,

unless the DOFE reviewer approves an alternative recommended by a DC-licensed PF

- Notes for Building Demolition, Razing, and Site Development Erosion shall be controlled by the installation of gutters and downspouts as soon as practicable.
- Measures shall be taken to achieve a non-eroding velocity for stormwater exiting from a roof or downspout or to emporarily pipe that stormwater directly to a storm drain The site work shall maximize the preservation of natural vegetation and limit the removal of vegetation to what is necessary
- for construction or landscaping activity. Remove off-site accumulations of sediment daily during construction and immediately at the request of a DOEE inspector.
- Filter water pumped from excavations prior to discharging to the storm sewer system. The DOEE inspector may require changes or additions to the ESC plan based on site conditions. Contractor to install straw bales or erosion control tube across stabilized construction entrances when not in use and at end

- DOEE SOIL EROSION AND SEDIMENT CONTROL PLAN GENERAL NOTES 1. Following initial land disturbance or re-disturbance, permanent or interim stabilization must be completed within seve (7) calendar days for the surfaces of all perimeter controls, dikes, swales, ditches, perimeter slopes, and slopes greater than three (3) horizontal to one (1) vertical (3:1); and fourteen (14) days for all other disturbed or graded areas on the project site. These requirements do not apply to areas shown on the plan that are used for material storage other than
- stockpiling, or for those areas on the plan where actual construction activities are being performed. Maintenance shall be performed as necessary so that stabilized areas continuously meet the appropriate requirements of the District of Columbia Standards and Specifications for Soil Erosion and Sediment Control (ESC). [21 DCMR § 542.9 (o)]
- ESC measures shall be in place before and during land disturbance. [21 DCMR § 543.6] 3. Contact DOEE Inspection (202) 535-2977 to schedule a preconstruction meeting at least three (3) business days before the commencement of a land-disturbing activity. [21 DCMR § 503.7 (a)] 4. A copy of the approved plan set will be maintained at the construction site from the date that construction activities
- begin to the date of final stabilization and will be available for DOEE inspectors. [21 DCMR § 542.15] 5. ESC measures shall be in place to stabilize an exposed area as soon as practicable after construction activity has temporarily or permanently ceased but no later than fourteen (14) days following cessation, except that temporary or permanent stabilization shall be in place at the end of each day of underground utility work that is not contained within
- a larger development site. [21 DCMR § 543.7] 6. Stockpiled material being actively used during a phase of construction shall be protected against erosion by establish and maintaining perimeter controls around the stockpile. [21 DCMR § 543.16 (a)] 7. Stockpiled material not being actively used or added to shall be stabilized with mulch, temporary vegetation, hydro-
- seed or plastic within fifteen (15) calendar days after its last use or addition. [21 DCMR § 543.16 (b)] health hazard to the public or may be detrimental to surface or ground water quality, or which may cause damage to property or the drainage system. All fill material must be free of hazardous materials and comply with all applicable
- District and federal regulations. 9. Protect best management practices from sedimentation and other damage during construction for proper post
- construction operation. [21 DCMR § 543.5] 10. Request a DOEE inspector's approval after the installation of perimeter erosion and sediment controls, but before proceeding with any other earth disturbance or grading. [21 DCMR § 542.12 (a)] 11. Request a DOEE inspector's approval after final stabilization of the site and before the removal of erosion and sediment 12. Final stabilization means that all land-disturbing activities at the site have been completed and either of the following two criteria have been met: (1) a uniform (for example, evenly distributed, without large bare areas) perennial
- vegetative cover with a density of seventy percent (70%) of the native background vegetative cover for the area has been established on all unpayed areas and areas not covered by permanent structures, or (2) equivalent permanent stabilization measures have been employed (such as the use of riprap, gabions, or geotextiles). [21 DCMR § 542.12 (b.1
- 13. Follow the requirements of the United States Environmental Protection Agency approved Stormwater Pollution Prevention Plan (SWPPP) and maintain a legible copy of this SWPPP on site. [21 DCMR § 543.10 (b)] 14. Post a sign that notifies the public to contact DOEE in the event of erosion or other pollution. The sign will be placed at each entrance to the site or as directed by the DOEE inspector. Each sign will be no less than 18 x 24 inches in size and made of materials that will withstand weather for the duration of the project. Lettering will be at least 1 inch in height and easily readable by the public from a distance of twelve feet (12 ft). The sign must direct the public, in substantially the following form: "To Report Erosion, Runoff. or Stormwater Pollution" and will provide the construction site address

DOEE's telephone number (202-535-2977). DOEE's e-mail address (IEB.scheduling@dc.gov), and the 311 mobile app

shall keep on site proof of professional licensing or of successful completion of a DOEE-approved training program. [21

heading ("Construction-Erosion Runoff"). [21 DCMR § 543.22] If a site disturbs 5,000 square feet of land or greater, the ESC plan must 15. A Responsible Person must be present or available while the site is in a land-disturbing phase. The Responsible Person is charged with being available to (a) inspect the site and its ESC measures at least once biweekly and after a rainfall event to identify and remedy each potential or actual erosion problem, (b) respond to each potential or actual erosion problem identified by construction personnel, and (c) speak on site with DOEE to remedy each potential or actual erosion problem. A Responsible Person shall be (a) licensed in the District of Columbia as a civil or geotechnical engineer a land surveyor, or architect; or (b) certified through a training program that DOEE approves, including a course on erosion control provided by another jurisdiction or professional association. During construction, the Responsible Person
